$\frac{d}{dt}$ changes a function $f(t)$ into a new function $f'(t)$.

$\frac{d}{dt}$ changes a function $f(t)$ into a new function $f'(t)$.

$\mathcal{L}$ changes a function $f(t)$ into a new function $F(s)$.

$\frac{d}{dt}$ changes a function $f(t)$ into a new function $f'(t)$.

$\mathcal{L}$ changes a function $f(t)$ into a new function $F(s)$.

The **Laplace Transform** of $f : [0, \infty) \to \mathbb{R}$ is a new function defined by

Using integration by parts ($\int_a^b uv' = [uv]_a^b - \int_a^b u'v$), we have

$$G(s) = \mathcal{L}\big[g\big](s) = \int_0^\infty e^{-st} \sin at \, dt = \lim_{R \to \infty} \int_0^R e^{-st} \sin at \, dt$$

$$= \lim_{R \to \infty} \left(\right)$$

$$F(s) = \mathcal{L}\big[f\big](s) = \int_0^\infty e^{-st} f(t) \ dt$$

Example

$$= \lim_{R\to\infty} \left(\left[-\frac{1}{a} e^{-st} \cos at \right]_0^R - \frac{s}{a} \int_0^R e^{-st} \cos at \ dt \right)$$

$$=$$

$$F(s) = \mathcal{L}\big[f\big](s) = \int_0^\infty e^{-st} f(t)\ dt$$

Example

Find the Laplace Transform of $g(t) = \sin at\ (t \geq 0)$.

Using integration by parts $(\int_a^b uv' = [uv]_a^b - \int_a^b u'v)$, we have

$$G(s) = \mathcal{L}\big[g\big](s) = \int_0^\infty e^{-st} \sin at\ dt = \lim_{R \to \infty} \int_0^R e^{-st}\sin at\ dt$$

$$= \lim_{R \to \infty} \left(\left[-\frac{1}{a}e^{-st}\cos at \right]_0^R - \frac{s}{a} \int_0^R e^{-st}\cos at\ dt \right)$$

$$= \frac{1}{a} - \frac{s}{a} \int_0^\infty e^{-st} \cos at\ dt.$$

$$G(s) = \int_0^\infty e^{-st} \sin at \, dt = \frac{1}{a} - \frac{s}{a} \int_0^\infty e^{-st} \cos at \, dt$$

Using integration by parts a second time, we have

$$G(s) = \int_0^\infty e^{-st} \sin at \, dt = \frac{1}{a} - \frac{s}{a} \int_0^\infty e^{-st} \cos at \, dt$$

Using integration by parts a second time, we have

$$G(s) = \frac{1}{a} - \frac{s^2}{a^2} \int_0^\infty e^{-st} \sin at \, dt$$

$$G(s) = \int_0^\infty e^{-st} \sin at \, dt = \frac{1}{a} - \frac{s}{a} \int_0^\infty e^{-st} \cos at \, dt$$

Using integration by parts a second time, we have

$$G(s) = \frac{1}{a} - \frac{s^2}{a^2} \int_0^\infty e^{-st} \sin at \, dt = \frac{1}{a} - \frac{s^2}{a^2} G(s).$$

$$G(s) = \int_0^\infty e^{-st} \sin at \, dt = \frac{1}{a} - \frac{s}{a} \int_0^\infty e^{-st} \cos at \, dt$$

Using integration by parts a second time, we have

> Find the inverse Laplace Transform of $F(s) = \ln\left(1 + \frac{1}{s^2}\right)$.

Again we will use the formula

$$\mathcal{L}\left[t^n f(t)\right] = (-1)^n \frac{d^n F}{ds^n}.$$

Find the inverse Laplace Transform of $F(s) = \ln\left(1 + \frac{1}{s^2}\right)$.

Again we will use the formula

$$\mathcal{L}\left[t^n f(t)\right] = (-1)^n \frac{d^n F}{ds^n}.$$

Setting $n = 1$

$$\mathcal{L}\left[t f(t)\right] = (-1)\frac{dF}{ds}$$

Example

Find the inverse Laplace Transform of $F(s) = \ln\left(1 + \frac{1}{s^2}\right)$.

Again we will use the formula

$$\mathcal{L}\left[t^n f(t)\right] = (-1)^n \frac{d^n F}{ds^n}.$$

Setting $n = 1$

$$\mathcal{L}\left[t f(t)\right] = (-1)\frac{dF}{ds}$$

and taking $\mathcal{L}^{-1}$ of both sides gives

$$t f(t) = -\mathcal{L}^{-1}\left[\frac{dF}{ds}\right].$$

$$F(s) = \ln\left(1 + \frac{1}{s^2}\right)$$

Now

$$\frac{dF}{ds} = \frac{d}{ds}\ln\left(1 + \frac{1}{s^2}\right)$$

$$F(s) = \ln\left(1 + \frac{1}{s^2}\right)$$

Now

$$\frac{dF}{ds} = \frac{d}{ds}\ln\left(1 + \frac{1}{s^2}\right) = \frac{\frac{-2}{s^3}}{\left(1 + \frac{1}{s^2}\right)}$$

$$F(s) = \ln\left(1 + \frac{1}{s^2}\right)$$

Now

$$\frac{dF}{ds} = \frac{d}{ds}\ln\left(1 + \frac{1}{s^2}\right) = \frac{\frac{-2}{s^3}}{\left(1 + \frac{1}{s^2}\right)} = \frac{-2}{s\left(s^2 + 1\right)}.$$

$$F(s) = \ln\left(1 + \frac{1}{s^2}\right)$$

Now

$$\frac{dF}{ds} = \frac{d}{ds}\ln\left(1 + \frac{1}{s^2}\right) = \frac{\frac{-2}{s^3}}{\left(1 + \frac{1}{s^2}\right)} = \frac{-2}{s\left(s^2 + 1\right)}.$$

Therefore

$$t f(t) = -\mathcal{L}^{-1}\left[\frac{dF}{ds}\right] = \mathcal{L}^{-1}\left[\frac{2}{s\left(s^2 + 1\right)}\right].$$

$$F(s) = \ln\left(1 + \frac{1}{s^2}\right)$$

Now

$$\frac{dF}{ds} = \frac{d}{ds}\ln\left(1 + \frac{1}{s^2}\right) = \frac{\frac{-2}{s^3}}{\left(1 + \frac{1}{s^2}\right)} = \frac{-2}{s\left(s^2 + 1\right)}.$$

Therefore

$$t f(t) = -\mathcal{L}^{-1}\left[\frac{dF}{ds}\right] = \mathcal{L}^{-1}\left[\frac{2}{s\left(s^2 + 1\right)}\right].$$

To proceed, we need to write $\frac{2}{s(s^2+1)}$ in partial fractions.

We calculate that

$$\frac{2}{s(s^2+1)} = \frac{A}{s} + \frac{Bs+C}{s^2+1}$$

We calculate that

$$\frac{2}{s\left(s^2+1\right)} = \frac{A}{s} + \frac{Bs+C}{s^2+1}$$

$$= \frac{A(s^2+1) + Bs^2 + Cs}{s\left(s^2+1\right)}$$

We calculate that

$$\frac{2}{s\,(s^2+1)} = \frac{A}{s} + \frac{Bs+C}{s^2+1}$$

$$= \frac{A(s^2+1) + Bs^2 + Cs}{s\,(s^2+1)}$$

$$= \frac{(A+B)s^2 + Cs + A}{s\,(s^2+1)}$$

We calculate that

$$\frac{2}{s\,(s^2+1)} = \frac{A}{s} + \frac{Bs+C}{s^2+1}$$

$$= \frac{A(s^2+1)+Bs^2+Cs}{s\,(s^2+1)}$$

$$= \frac{(A+B)s^2+Cs+A}{s\,(s^2+1)}$$

$$\implies \quad \begin{aligned} A &= 2 \\ B &= -2 \\ C &= 0 \end{aligned}$$

We calculate that

$$\frac{2}{s\,(s^2+1)} = \frac{A}{s} + \frac{Bs+C}{s^2+1}$$

$$= \frac{A(s^2+1) + Bs^2 + Cs}{s\,(s^2+1)}$$

$$= \frac{(A+B)s^2 + Cs + A}{s\,(s^2+1)}$$

$$= \frac{2}{s} - \frac{2s}{s^2+1}.$$

$$\implies \quad \begin{aligned} A &= 2 \\ B &= -2 \\ C &= 0 \end{aligned}$$

Thus

$$t f(t) = \mathcal{L}^{-1} \left[\frac{2}{s \left(s^2 + 1\right)} \right] = \mathcal{L}^{-1} \left[\frac{2}{s} - \frac{2s}{s^2 + 1} \right]$$

Thus

$$tf(t) = \mathcal{L}^{-1}\left[\frac{2}{s\,(s^2+1)}\right] = \mathcal{L}^{-1}\left[\frac{2}{s} - \frac{2s}{s^2+1}\right]$$

$f(t)$	$F(s) = \mathcal{L}\big[f\big](s)$	
1	$\frac{1}{s}$	$s > 0$
e^{at}	$\frac{1}{s-a}$	$s > a$
$t^n \quad (n \in \mathbb{N})$	$\frac{n!}{s^{n+1}}$	$s > 0$
$\sin at$	$\frac{a}{s^2+a^2}$	$s > 0$
$\cos at$	$\frac{s}{s^2+a^2}$	$s > 0$
$\sinh at$	$\frac{a}{s^2-a^2}$	$s > |a|$

Thus

$$tf(t) = \mathcal{L}^{-1}\left[\frac{2}{s(s^2+1)}\right] = \mathcal{L}^{-1}\left[\frac{2}{s} - \frac{2s}{s^2+1}\right]$$

$f(t)$	$F(s) = \mathcal{L}[f](s)$	
1	$\frac{1}{s}$	$s > 0$
e^{at}	$\frac{1}{s-a}$	$s > a$
$t^n \quad (n \in \mathbb{N})$	$\frac{n!}{s^{n+1}}$	$s > 0$
$\sin at$	$\frac{a}{s^2+a^2}$	$s > 0$
$\cos at$	$\frac{s}{s^2+a^2}$	$s > 0$
$\sinh at$	$\frac{a}{s^2-a^2}$	$s > |a|$

Thus

$$t f(t) = \mathcal{L}^{-1}\left[\frac{2}{s\left(s^2+1\right)}\right] = \mathcal{L}^{-1}\left[\frac{2}{s} - \frac{2s}{s^2+1}\right]$$

$f(t)$	$F(s) = \mathcal{L}\big[f\big](s)$	
1	$\frac{1}{s}$	$s > 0$
e^{at}	$\frac{1}{s-a}$	$s > a$
$t^n \quad (n \in \mathbb{N})$	$\frac{n!}{s^{n+1}}$	$s > 0$
$\sin at$	$\frac{a}{s^2+a^2}$	$s > 0$
$\cos at$	$\frac{s}{s^2+a^2}$	$s > 0$
$\sinh at$	$\frac{a}{s^2-a^2}$	$s > |a|$

Thus

$$t f(t) = \mathcal{L}^{-1}\left[\frac{2}{s\,(s^2+1)}\right] = \mathcal{L}^{-1}\left[\frac{2}{s} - \frac{2s}{s^2+1}\right]$$

$$\mathcal{L}\left[1\right] = \frac{1}{s} \qquad \mathcal{L}\left[\cos at\right] = \frac{s}{s^2+a^2}$$

Thus

$$tf(t) = \mathcal{L}^{-1}\left[\frac{2}{s\left(s^2+1\right)}\right] = \mathcal{L}^{-1}\left[\frac{2}{s} - \frac{2s}{s^2+1}\right]$$

$$= 2\mathcal{L}^{-1}\left[\frac{1}{s}\right] - 2\mathcal{L}^{-1}\left[\frac{s}{s^2+1}\right]$$

$$\mathcal{L}\left[1\right] = \frac{1}{s} \qquad\qquad \mathcal{L}\left[\cos at\right] = \frac{s}{s^2+a^2}$$

Thus

$$t f(t) = \mathcal{L}^{-1} \left[\frac{2}{s\left(s^2+1\right)} \right] = \mathcal{L}^{-1} \left[\frac{2}{s} - \frac{2s}{s^2+1} \right]$$

$$= 2\mathcal{L}^{-1} \left[\frac{1}{s} \right] - 2\mathcal{L}^{-1} \left[\frac{s}{s^2+1} \right]$$

$$= 2 - 2\cos t.$$

$$\mathcal{L}\left[1\right] = \frac{1}{s} \qquad\qquad \mathcal{L}\left[\cos at\right] = \frac{s}{s^2+a^2}$$

Thus

$$tf(t) = \mathcal{L}^{-1}\left[\frac{2}{s\left(s^2+1\right)}\right] = \mathcal{L}^{-1}\left[\frac{2}{s} - \frac{2s}{s^2+1}\right]$$

$$= 2\mathcal{L}^{-1}\left[\frac{1}{s}\right] - 2\mathcal{L}^{-1}\left[\frac{s}{s^2+1}\right]$$

$$= 2 - 2\cos t.$$

Therefore

$$\boxed{f(t) = \frac{2\left(1-\cos t\right)}{t}.}$$

$$\mathcal{L}\left[1\right] = \frac{1}{s} \qquad\qquad \mathcal{L}\left[\cos at\right] = \frac{s}{s^2+a^2}$$

solution 1 (method from Chapter 3): The characteristic equation
$$0 = r^2 - r - 2 = (r - 2)(r + 1)$$

has roots $r_1 = -1$ and $r_2 = 2$. So $y = c_1 e^{-t} + c_2 e^{2t}$. Using the initial conditions we find that $c_1 = \frac{2}{3}$ and $c_2 = \frac{1}{3}$. Therefore

$$\boxed{y(t) = \frac{2}{3} e^{-t} + \frac{1}{3} e^{2t}.}$$

solution 2 (Laplace Transform):

solution 2 (Laplace Transform):

solution 2 (Laplace Transform):

$$y'' - y' - 2y = 0$$

First we take the Laplace Transform of the ODE

$$\mathcal{L}\big[y'' - y' - 2y\big] = \mathcal{L}\big[0\big]$$

$$y'' - y' - 2y = 0$$

$$\mathcal{L}\left[y''\right] = s^2 Y - sy(0) - y'(0) \qquad \mathcal{L}\left[y'\right] = sY - y(0)$$

First we take the Laplace Transform of the ODE

$$\mathcal{L}\left[y'' - y' - 2y\right] = \mathcal{L}\left[0\right]$$

$$\mathcal{L}\left[y''\right] - \mathcal{L}\left[y'\right] - 2\mathcal{L}\left[y\right] = 0$$

$$y'' - y' - 2y = 0$$

$$\mathcal{L}\left[y''\right] = s^2 Y - sy(0) - y'(0) \qquad \mathcal{L}\left[y'\right] = sY - y(0)$$

First we take the Laplace Transform of the ODE

$$\mathcal{L}\left[y'' - y' - 2y\right] = \mathcal{L}\left[0\right]$$

$$\mathcal{L}\left[y''\right] - \mathcal{L}\left[y'\right] - 2\mathcal{L}\left[y\right] = 0$$

It follows that

$$\left(s^2 Y - sy(0) - y'(0)\right) - \left(sY - y(0)\right) - 2Y = 0$$

$$y'' - y' - 2y = 0$$

$$\mathcal{L}\left[y''\right] = s^2 Y - sy(0) - y'(0) \qquad \mathcal{L}\left[y'\right] = sY - y(0)$$

First we take the Laplace Transform of the ODE

$$\mathcal{L}\left[y'' - y' - 2y\right] = \mathcal{L}\left[0\right]$$

$$\mathcal{L}\left[y''\right] - \mathcal{L}\left[y'\right] - 2\mathcal{L}\left[y\right] = 0$$

It follows that

$$\left(s^2 Y - sy(0) - y'(0)\right) - \left(sY - y(0)\right) - 2Y = 0$$
$$\left(s^2 Y - s - 0\right) - \left(sY - 1\right) - 2Y = 0$$
$$(s^2 - s - 2)Y + (1 - s) = 0.$$

Thus

$$Y(s) = \frac{s-1}{s^2 - s - 2} = \frac{s-1}{(s-2)(s+1)}.$$

Thus

$$Y(s) = \frac{s-1}{s^2 - s - 2} = \frac{s-1}{(s-2)(s+1)}.$$

Using partial fractions we obtain

$$Y(s) = \frac{s-1}{(s-2)(s+1)} = \frac{A}{s-2} + \frac{B}{s+1} = \frac{As + A + Bs - 2B}{(s-2)(s+1)}$$

$$= \frac{1}{3}\left(\frac{1}{s-2}\right) + \frac{2}{3}\left(\frac{1}{s+1}\right).$$

Thus
$$Y(s) = \frac{s-1}{s^2 - s - 2} = \frac{s-1}{(s-2)(s+1)}.$$

Using partial fractions we obtain

$$Y(s) = \frac{s-1}{(s-2)(s+1)} = \frac{A}{s-2} + \frac{B}{s+1} = \frac{As + A + Bs - 2B}{(s-2)(s+1)}$$
$$= \frac{1}{3}\left(\frac{1}{s-2}\right) + \frac{2}{3}\left(\frac{1}{s+1}\right).$$

But recall that $\mathcal{L}\left[e^{2t}\right] = \frac{1}{s-2}$ and $\mathcal{L}\left[e^{-t}\right] = \frac{1}{s+1}$.

Thus

$$Y(s) = \frac{s-1}{s^2 - s - 2} = \frac{s-1}{(s-2)(s+1)}.$$

Using partial fractions we obtain

$$Y(s) = \frac{s-1}{(s-2)(s+1)} = \frac{A}{s-2} + \frac{B}{s+1} = \frac{As + A + Bs - 2B}{(s-2)(s+1)}$$

$$= \frac{1}{3}\left(\frac{1}{s-2}\right) + \frac{2}{3}\left(\frac{1}{s+1}\right).$$

But recall that $\mathcal{L}\left[e^{2t}\right] = \frac{1}{s-2}$ and $\mathcal{L}\left[e^{-t}\right] = \frac{1}{s+1}$. Therefore

$$y(t) = \mathcal{L}^{-1}\left[Y\right] = \frac{1}{3}\mathcal{L}^{-1}\left[\frac{1}{s-2}\right] + \frac{2}{3}\mathcal{L}^{-1}\left[\frac{1}{s+1}\right] = \boxed{\frac{1}{3}e^{2t} + \frac{2}{3}e^{-t}.}$$

$$= 2\mathcal{L}\left[\cos t\right] + \frac{5}{3}\mathcal{L}\left[\sin t\right] - \frac{1}{3}\mathcal{L}\left[\sin 2t\right].$$

Therefore

$$\boxed{y(t) = 2\cos t + \frac{5}{3}\sin t - \frac{1}{3}\sin 2t.}$$

Example

Solve

$$\begin{cases} y^{(4)} - y = 0 \\ y(0) = 0 \\ y'(0) = 1 \\ y''(0) = 0 \\ y'''(0) = 0. \end{cases}$$

Example

Solve

$$\begin{cases} y^{(4)} - y = 0 \\ y(0) = 0 \\ y'(0) = 1 \\ y''(0) = 0 \\ y'''(0) = 0. \end{cases}$$

Using the Laplace Transform we calculate that

$$0 = \mathcal{L}\left[y^{(4)}\right] - \mathcal{L}\left[y\right]$$

$$=$$

$$=$$

Example

Solve

$$\begin{cases} y^{(4)} - y = 0 \\ y(0) = 0 \\ y'(0) = 1 \\ y''(0) = 0 \\ y'''(0) = 0. \end{cases}$$

Using the Laplace Transform we calculate that

$$0 = \mathcal{L}\left[y^{(4)}\right] - \mathcal{L}\left[y\right]$$
$$= \left(s^4 Y - s^3 y(0) - s^2 y'(0) - sy''(0) - y'''(0)\right) - Y$$
$$=$$

Example

Solve
$$\begin{cases} y^{(4)} - y = 0 \\ y(0) = 0 \\ y'(0) = 1 \\ y''(0) = 0 \\ y'''(0) = 0. \end{cases}$$

Using the Laplace Transform we calculate that

$$\begin{aligned} 0 &= \mathcal{L}\left[y^{(4)}\right] - \mathcal{L}\left[y\right] \\ &= \left(s^4 Y - s^3 y(0) - s^2 y'(0) - s y''(0) - y'''(0)\right) - Y \\ &= s^4 Y - s^2 - Y = (s^4 - 1)Y - s^2. \end{aligned}$$

$$0 = (s^4 - 1)Y - s^2$$

Thus

$$Y(s) = \frac{s^2}{s^4 - 1}$$

$$0 = (s^4 - 1)Y - s^2$$

Thus

$$Y(s) = \frac{s^2}{s^4 - 1} = \frac{s^2}{(s^2 - 1)(s^2 + 1)}$$

$$0 = (s^4 - 1)Y - s^2$$

Thus

$$Y(s) = \frac{s^2}{s^4 - 1} = \frac{s^2}{(s^2 - 1)(s^2 + 1)} = \frac{\frac{1}{2}}{s^2 - 1} + \frac{\frac{1}{2}}{s^2 + 1}.$$

$$0 = (s^4 - 1)Y - s^2$$

Thus

$$Y(s) = \frac{s^2}{s^4 - 1} = \frac{s^2}{(s^2 - 1)(s^2 + 1)} = \frac{\frac{1}{2}}{s^2 - 1} + \frac{\frac{1}{2}}{s^2 + 1}.$$
Therefore

$$y = \frac{1}{2}\mathcal{L}^{-1}\left[\frac{1}{s^2 - 1}\right] + \frac{1}{2}\mathcal{L}^{-1}\left[\frac{1}{s^2 + 1}\right] = \boxed{\frac{1}{2}\sinh t + \frac{1}{2}\sin t.}$$

$$\begin{cases} y^{(4)} - y = 0 \\ y(0) = 0 \\ y'(0) = 1 \\ y''(0) = 0 \\ y'''(0) = 0. \end{cases}$$

$$y(t) = \tfrac{1}{2}\sinh t + \tfrac{1}{2}\sin t$$
